

## Problem Set 12, Dec 3, 2020 (Solutions to SVD Theory Questions)

### Problem 1 (How to compute $U$ and $S$ efficiently):

Consider the  $N \times N$  matrix  $X^\top X$ . Similarly as before, we have

$$X^\top X = V S^\top S V^\top.$$

Let  $v_i, i = 1, \dots, D$ , denote the columns of  $V$ . Then

$$X^\top X v_j = V S^\top S V^\top v_j = s_j^2 v_j. \quad (1)$$

So we see that the  $j$ -th column of  $V$  is an eigenvector of  $X^\top X$  with eigenvalue  $s_j^2$ . Therefore, solving the eigenvector/value problem for the matrix  $X^\top X$  gives us a way to compute  $V$  and  $S$ .

Now multiply the identity (1) from the left by the matrix  $X$ . We get

$$X X^\top (X v_j) = s_j^2 (X v_j).$$

We see therefore that  $u_j = X v_j$  and so we can compute the desired eigenvectors  $u_j$  from the eigenvectors  $v_j$  without having to solve the  $D \times D$  eigenvector/value problem.

### Problem 2 (Positive semi-definite):

Consider  $A = X X^\top$  and  $B = X^\top X$ . By the SVD we know that  $X = U S V^\top$ . As we discussed in the course, the columns of  $U$  are eigenvectors of the first matrix and the columns of  $V$  are eigenvectors of the second matrix. But note that  $A = B$  since  $X$  is symmetric. Hence the eigenspace associated to each distinct eigenvalue of  $A$  is equal to the eigenspace associated to the same eigenvalue of  $B$ .

Set  $U = V$  and let the columns of  $U$  be eigenvectors of  $A$ . Compute  $U^\top X V$ . This gives us a diagonal matrix which we can define to be  $S$ . It's entries are not necessarily non-negative.

If the matrix is in addition positive semi-definite then the diagonal entries of  $S$  must in fact must be non-negative – multiplying the matrix from the left by  $u_j^\top$  and from the right by  $u_j$  gives  $s_j$  which must be non-negative if the quadratic form given by the matrix is assumed to be positive-definite.
